# Clothes and environment

---

Trachana Marianna

# Production

---

The production of clothes is a complex process as today the clothes are produced from many different chemical precursors such as plastic.

# Clothes

---

The clothing production process varies according to the quality and materials used

- high-quality and tailor-made clothes leave a smaller energy footprint on the environment as they are produced from materials that do not have a strong impact on the environment.
- unlike lower quality clothes have a greater impact on the environment as the materials they are produced with are based on chemicals.

# Non-renewable energy sources

---

petroleum is a very common material for the production of clothes

- Petroleum derivatives such as polyester are used for the composition of clothing. However, mass production and the continuous use of non-renewable energy sources cause a dramatic reduction of these resources.

# The factories

---

But the same factories burden the environment to a great extent

## Machines

- The machines in the factories and also in the industries need fuel which during their combustion release gases which burden the planet

## Waste

- Factory waste ends up in the seas, rivers and lakes, this results in the continuous contamination of the aquatic habitat and the continuous contamination of the human body

# How we can solve that problem

---

First of all we could limit the over-consumption of our earth's natural resources and replace them with new environmentally friendly.

Also we can technically build a place to deposit the factory waste.

In the end we can built eco friendly factories that the couldn't pollute the environment.

# THANK YOU!
